Chapter 1

Signatures

A *signature* is a collection of definitions, including terms, tactics and theorems.

1.1 Grammar

The grammar of `Red JonPRL` signatures is presented in Figure 1.1. Note that an optional production of sort s is formatted $\langle s \rangle$ in the rules.

sigexp	::=	$\langle \cdot \rangle$	empty signature
		sigexp sigdec.	signature extension
sigdec	::=	`Def` *opid*$\langle[params]\rangle\langle(args)\rangle : sortid = [term]$	operator definition
		`Tac` *opid*$\langle[params]\rangle\langle(args)\rangle = [term]$	tactic definition
		`Thm` *opid*$\langle[params]\rangle\langle(args)\rangle : [term]$ `by` $[term]$	theorem declaration
params	::=	$\langle \cdot \rangle$	empty parameter list
		params, symbind	parameter list extension
args	::=	$\langle \cdot \rangle$	empty argument list
		args, metabind	argument list extension
symbind	::=	*symid : sortid*	symbol binding
metabind	::=	*metaid : valence*	metavariable binding
valence	::=	$\langle\langle\{sortlist\}\rangle\langle[sortlist]\rangle.\rangle sortid$	valence
sortlist	::=	$\langle \cdot \rangle$	empty sort list
		sortlist, sortid	sort list extension

Figure 1.1: Grammar of signature expressions. The identifier sorts *opid*, *sortid*, *symid* and *metaid* can be assumed to be arbitrary strings; the sort *term* is left uninterpreted.

1.2 Static Semantics

The static semantics for `Red JonPRL` signatures begins with a specification of the class of *semantic* objects that will serve as the meanings for the *syntactic* objects defined in Section 1.1. We assume an ambient abstract binding tree signature such that at least the following facts hold:

$$\frac{}{\texttt{tac } sort} \qquad \frac{}{\texttt{thm } sort} \qquad \frac{}{\texttt{exp } sort} \qquad \frac{}{\texttt{opid } sort}$$

$$\frac{}{\Upsilon \Vdash \texttt{prove} : (.\,\texttt{exp},.\,\texttt{tac})\,\texttt{thm}}$$

Then, our semantic objects are defined as in Figure 1.2.

$$
\begin{array}{rcll}
a, b & \in & \text{Sym} & \\
\mathfrak{m}, \mathfrak{n} & \in & \text{Metavar} & \\
\sigma, \tau & \in & \text{Sort} & \triangleq \{\,\tau \mid \tau\ \textit{sort}\,\} \\
v & \in & \text{ProdValence} & \triangleq \{\,v \mid v\ \textit{valence}\,\} \\
\vartheta & \in & \text{Opid} & \triangleq \text{Sym} \\
\Upsilon & \in & \text{Params} & \triangleq \text{Sym} \rightharpoonup \text{Sort} \\
\Theta & \in & \text{Args} & \triangleq \text{Metavar} \rightharpoonup \text{ProdValence} \\
M, N & \in & \text{Tm}(\Theta, \Upsilon, \tau) & \triangleq \{\,M \mid \Theta \triangleright \Upsilon \parallel \cdot \vdash M : \tau\,\} \\
D & \in & \text{Decl} & \triangleq \coprod_{\Upsilon, \Theta, \tau} \text{Tm}(\Theta, \Upsilon, \tau) \\
\Sigma & \in & \text{Sig} & \triangleq \text{Opid} \rightharpoonup \text{Decl}
\end{array}
$$

Figure 1.2: Specification of the semantic objects.

A *natural semantics* hinges on the elaboration judgment $E \vdash A \Longrightarrow A'$, which means that the syntactic object A elaborates to the semantic object A' in the environment E. Let the $\Upsilon_\Sigma \in \text{Params}$ be defined as follows:

$$\Upsilon_\Sigma(\vartheta) \triangleq \begin{cases} \texttt{opid} & \textit{if} \quad \vartheta \in \mathbf{dom}(\Sigma) \\ \bot & \textit{otherwise} \end{cases}$$

Symbol Bindings

$$\boxed{\Sigma \vdash \textit{symbind} \Longrightarrow (a, \tau)}$$

$$\frac{\Sigma \vdash \textit{symid} \Longrightarrow a \quad \Sigma \vdash \textit{sortid} \Longrightarrow \tau}{\Sigma \vdash \textit{symid} : \textit{sortid} \Longrightarrow (a, \tau)} \tag{1.1}$$

Metavariable Bindings

$$\boxed{\Sigma \vdash \textit{metabind} \Longrightarrow (\mathfrak{m}, v)}$$

$$\frac{\Sigma \vdash \textit{metaid} \Longrightarrow \mathfrak{m} \quad \Sigma \vdash \textit{valence} \Longrightarrow v}{\Sigma \vdash \textit{metaid} : \textit{valence} \Longrightarrow (\mathfrak{m}, v)} \tag{1.2}$$

Parameters

$$\boxed{\Sigma \vdash \textit{params} \Longrightarrow \Upsilon}$$

$$\frac{}{\Sigma \vdash \langle \cdot \rangle \Longrightarrow \{\}} \tag{1.3}$$

$$\frac{\Sigma \vdash \textit{params} \Longrightarrow \Upsilon \quad \Sigma \vdash \textit{symbind} \Longrightarrow (a, \tau)}{\Sigma \vdash \textit{params}, \textit{symbind} \Longrightarrow \Upsilon \cup a \mapsto \tau} \tag{1.4}$$

Arguments

$$\boxed{\Sigma \vdash \textit{args} \Longrightarrow \Theta}$$

$$\frac{}{\Sigma \vdash \langle \cdot \rangle \Longrightarrow \{\}} \tag{1.5}$$

$$\frac{\Sigma \vdash \textit{args} \Longrightarrow \Theta \quad \Sigma \vdash \textit{metabind} \Longrightarrow (\mathfrak{m}, v)}{\Sigma \vdash \textit{args}, \textit{metabind} \Longrightarrow \Theta \cup \mathfrak{m} \mapsto v} \tag{1.6}$$

Operator Identifiers

$$\boxed{\Sigma \vdash \mathit{opid} \Longrightarrow \vartheta}$$

$$\frac{\vartheta \notin \mathbf{dom}(\Sigma)}{\Sigma \vdash \mathit{opid} \Longrightarrow \vartheta} \tag{1.7}$$

Declarations

$$\boxed{\Sigma \vdash \mathit{sigdec} \Longrightarrow (\vartheta, D)}$$

$$\frac{\Sigma \vdash \mathit{params} \Longrightarrow \Upsilon \quad \Sigma \vdash \mathit{sortid} \Longrightarrow \tau \quad \Sigma \vdash \mathit{opid} \Longrightarrow \vartheta \quad \Sigma \vdash \mathit{args} \Longrightarrow \Theta \quad \Sigma \vdash \mathit{term} \Longrightarrow M \quad \Theta \rhd \Upsilon_{\Sigma} \oplus \Upsilon \parallel \cdot \vdash M : \tau}{\Sigma \vdash \mathtt{Def}\ \mathit{opid}\langle[\mathit{params}]\rangle\langle(\mathit{args})\rangle : \mathit{sortid} = [\mathit{term}] \Longrightarrow (\vartheta, \langle \Upsilon, \Theta, \tau, M \rangle)} \tag{1.8}$$

$$\frac{\Sigma \vdash \mathit{params} \Longrightarrow \Upsilon \quad \Sigma \vdash \mathit{args} \Longrightarrow \Theta \quad \Sigma \vdash \mathit{opid} \Longrightarrow \vartheta \quad \Sigma \vdash \mathit{term} \Longrightarrow M \quad \Theta \rhd \Upsilon_{\Sigma} \oplus \Upsilon \parallel \cdot \vdash M : \mathtt{tac}}{\Sigma \vdash \mathtt{Tac}\ \mathit{opid}\langle[\mathit{params}]\rangle\langle(\mathit{args})\rangle = [\mathit{term}] \Longrightarrow (\vartheta, \langle \Upsilon, \Theta, \mathtt{tac}, M \rangle)} \tag{1.9}$$

$$\frac{\Sigma \vdash \mathit{params} \Longrightarrow \Upsilon \quad \Sigma \vdash \mathit{term}_1 \Longrightarrow P \quad \Theta \rhd \Upsilon_{\Sigma} \oplus \Upsilon \parallel \cdot \vdash P : \mathtt{exp} \quad \Sigma \vdash \mathit{opid} \Longrightarrow \vartheta \quad \Sigma \vdash \mathit{args} \Longrightarrow \Theta \quad \Sigma \vdash \mathit{term}_2 \Longrightarrow M \quad \Theta \rhd \Upsilon_{\Sigma} \oplus \Upsilon \parallel \cdot \vdash M : \mathtt{tac}}{\Sigma \vdash \mathtt{Thm}\ \mathit{opid}\langle[\mathit{params}]\rangle\langle(\mathit{args})\rangle : [\mathit{term}_1]\ \mathtt{by}\ [\mathit{term}_2] \Longrightarrow (\vartheta, \langle \Upsilon, \Theta, \mathtt{thm}, \mathtt{prove}(P; M) \rangle)} \tag{1.10}$$

Signatures

$$\boxed{\vdash \mathit{sigexp} \Longrightarrow \Sigma}$$

$$\frac{}{\vdash \langle \cdot \rangle \Longrightarrow \{\}} \tag{1.11}$$

$$\frac{\vdash \mathit{sigexp} \Longrightarrow \Sigma \quad \Sigma \vdash \mathit{sigdec} \Longrightarrow (\vartheta, D)}{\vdash \mathit{sigexp}\ \mathit{sigdec}. \Longrightarrow \Sigma \cup \vartheta \mapsto D} \tag{1.12}$$

4

Chapter 2

Nominal LCF: a language for tactics

In a sequent calculus, left rules add hypotheses to the context; for instance, consider the left rule for positive conjunctions:

$$\frac{H, x : A \otimes B, y : A, z : B \gg [\langle y, z \rangle \,/\, x]\, C}{H, x : A \otimes B \gg C} \otimes_L^{x,y,z}$$

From a proof refinement perspective (see [1]), such a rule is typically manifested as an ML tactic $\otimes_L[x,y,z]$ which takes three names as parameters: the target hypothesis x, and the names to use for the new hypotheses y, z. However, whilst the identity of the name x is essential to the meaning of the tactic, the names supplied for the generated hypotheses can be freshly renamed with impunity.

Indeed, in a proof term assignment for this sequent calculus, the corresponding elimination form would *bind* variables x, y rather than take them as parameters. However, in the standard LCF tactic paradigm, it is not possible to reproduce this structure, because the sequencing of rules is mediated by the general purpose THEN tactical, which has no knowledge of names or binding.

We will design a language for tactics called **Nominal LCF** which supports a distinction between names bound and names taken as parameters, and then show how it can be elaborated into standard LCF.

2.1 The LCF Metalanguage

The essence of the LCF tactic system is captured by fixing a type *judgment* of judgments and *evidence* of evidence, and then using them to define the notion of a proof state and a tactic:

$$state \triangleq judgment\ list \otimes (evidence\ list \rightharpoonup evidence)$$
$$tactic \triangleq judgment \rightharpoonup state$$

In other words, a tactic is a partial function that takes a goal to its subgoals, and specifies how to transform the evidence of its subgoals into the evidence for the main goal. In the case of the sequence calculus we were considering, *judgment* would be a type of sequents.

Standard LCF Tacticals   There are a number of useful tacticals (higher order tactics) that can be defined for the LCF metalanguage. In particular, we have the following sequencing tacticals:

$$\texttt{THEN} \in tactic \otimes tactic \rightarrow tactic$$
$$\texttt{THENL} \in tactic \otimes tactic\ list \rightarrow tactic$$
$$\texttt{THENF} \in tactic \otimes \mathbb{N} \otimes tactic \rightarrow tactic$$

5

The $\text{THEN}(T_1, T_2)$ tactical applies T_1 to the goal, and then applies T_2 to all the subgoals generated by T_1; $\text{THENL}(T, \vec{T})$ is similar, except that it applies the list $\vec{T}$ of tactics pointwise to the subgoals generated by the application of T; finally, $\text{THENF}(T_1, i, T_2)$ applies T_2 to the ith subgoal generated by T_1. If co-lists are used instead of lists, then all three tactics can be defined in terms of THENL.

Nominal tactics and their continuity Now, frequently a tactic may need to consume names from a name store, which can be represented as infinite stream (choice sequence) of *atoms* or *symbols*; let $\mathbb{A}$ be the type of atoms; then, a *nominal tactic* is a function from choice sequences of atoms to tactics, $\mathbb{A}^{\mathbb{N}} \to tactic$.

Left sequent rules can be coded as nominal tactics, pulling the names for their bound variables from the supplied choice sequence of atoms; moreover, every such tactic is *continuous* in a specific sense. For a choice sequence $\alpha \in \mathbb{A}^{\mathbb{N}}$ and a natural number $n \in \mathbb{N}$, let $\overline{\alpha}[n]$ be the initial segment of α of length n; let $[n]\overline{\alpha}$ be infinite suffix of α got by chopping off the initial prefix $\overline{\alpha}[n]$. Let $M \approx N$ be *observational equivalence*: M and N evaluate to equal values, or they both diverge.

Then, for any nominal tactic T and judgment J, we can calculate a modulus of continuity:

$$\forall \alpha \in \mathbb{A}^{\mathbb{N}}. \exists n \in \mathbb{N}. \forall \beta \in \mathbb{A}^{\mathbb{N}}. \overline{\alpha}(n) = \overline{\beta}(n) \implies T(\alpha, J) \approx T(\beta, J) \qquad \text{(continuity)}$$

This calculation can be realized computationally in our metalanguage in a number of ways, but for our purposes it suffices to remark that it is a fact concerning all computable stream processors. Let $\mathsf{M}(T) \in judgment \to \mathbb{A}^{\mathbb{N}} \to \mathbb{N}$ calculate the modulus of continuity for a nominal tactic $T \in \mathbb{A}^{\mathbb{N}} \to tactic$ with name store α.

2.2   Nominal LCF

We will define the **Nominal LCF** language by specifying an abt signature for it; at its heart is decomposition of the various sequencing tacticals THEN, THENL, etc. of LCF into a single sequencing tactical combined a separate notion of *multi-tactic*. First, we define sorts for nominal tactics and multi-tactics respectively, as well as a sort for hypothesis names:

$$\overline{\texttt{tac } sort} \qquad \overline{\texttt{mtac } sort} \qquad \overline{\texttt{hyp } sort}$$

Now, we'll define the operators of **Nominal LCF**; note that the atomic tactics like $\texttt{id}$, $\texttt{fail}$ and $\texttt{elim}[a]$ are arbitrary and included only for the sake of illustration.

$$\overline{\Upsilon \Vdash \texttt{id} : ()\,\texttt{tac}} \qquad \overline{\Upsilon \Vdash \texttt{fail} : ()\,\texttt{tac}} \qquad \overline{\Upsilon, a : \texttt{hyp} \Vdash \texttt{elim}[a] : ()\,\texttt{tac}}$$

$$\overline{\Upsilon \Vdash \texttt{fix} : ([\texttt{tac}].\,\texttt{tac})\,\texttt{tac}} \qquad \overline{\Upsilon \Vdash \texttt{let} : (.\,\texttt{tac}, [\texttt{tac}].\,\texttt{tac})\,\texttt{tac}}$$

$$\frac{n \in \mathbb{N}}{\Upsilon \Vdash \texttt{seq}_n : (.\,\texttt{tac}, \{\texttt{hyp}^n\}.\,\texttt{mtac})\,\texttt{tac}} \qquad \overline{\Upsilon \Vdash \texttt{smoosh} : (.\,\texttt{tac}, .\,\texttt{tac})\,\texttt{tac}}$$

$$\overline{\Upsilon \Vdash \texttt{all} : (.\,\texttt{tac})\,\texttt{mtac}} \qquad \frac{n \in \mathbb{N}}{\Upsilon \Vdash \texttt{each}_n : (.\,\texttt{tac}^n)\,\texttt{mtac}} \qquad \frac{i \in \mathbb{N}}{\Upsilon \Vdash \texttt{some}_i : (.\,\texttt{tac})\,\texttt{mtac}}$$

6

For the sake of clarity, we introduce the following notational abbreviations for tactic expressions:

$$t_1; t_2 \triangleq \mathtt{seq}_0(.t_1;.t_2)$$

$$a_0, \ldots, a_n \leftarrow t_1; t_2 \triangleq \mathtt{seq}_n(.t_1; \{a_0, \ldots, a_n\}.t_2)$$

$$t_1 \duntap t_2 \triangleq \mathtt{smoosh}(.t_1;.t_n)$$

$$\Box t \triangleq \mathtt{all}(.t)$$

$$(\!|t_1, \ldots, t_n|\!) \triangleq \mathtt{each}_n(.t_1; \ldots; .t_n)$$

$$\Diamond_i t \triangleq \mathtt{some}_i(.t)$$

$$\mu x.\mathtt{t}[x] \triangleq \mathtt{fix}([x].\mathtt{t}[x])$$

$$let\ x := t_1\ in\ \mathtt{t}_2[x] \triangleq \mathtt{let}(.t_1; [x].\mathtt{t}_2[x])$$

2.2.1 Denotational Semantics

We will now give a denotational semantics for **Nominal LCF** by interpreting every tactic expression into an LCF nominal tactic. The intepretation $\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash t]\!]_\rho \equiv T$ is defined by recursion on $t : \mathtt{tac}$ such that $T \in \mathbb{A}^\mathbb{N} \to tactic$, presupposing that $\rho(x) \in \mathbb{A}^\mathbb{N} \to tactic$ for each $x : \mathtt{tac} \in \Gamma$. To start with, variable tactics are simply projected from the environment ρ:

$$\overline{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash x]\!]_\rho \equiv \rho(x)}$$

The basic tacticals are interpreted as follows (we omit the interpretation of $\mathtt{elim}[a]$, which will depend on the logic):

$$\overline{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash \mathtt{id}]\!]_\rho \equiv \lambda \alpha.\mathtt{ID}} \qquad \overline{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash \mathtt{fail}]\!]_\rho \equiv \lambda \alpha.\mathtt{FAIL}}$$

$$\frac{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash t_1]\!]_\rho \equiv T_1 \quad \mathcal{M} [\![\Upsilon \parallel \Gamma, x : \mathtt{tac} \vdash \mathtt{t}_2[x]]\!]_{\rho, x \mapsto T_1} \equiv T_2}{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash let\ x := t_1\ in\ \mathtt{t}_2[x]]\!]_\rho \equiv T_2}$$

$$\overline{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash \mu x.\mathtt{t}[x]]\!]_\rho \equiv \mathtt{fix}\left(\lambda T.\mathcal{M} [\![\Upsilon \parallel \Gamma, x : \mathtt{tac} \vdash \mathtt{t}[x]]\!]_{\rho, x \mapsto T} \right)}$$

The rule for the *smoosh* tactical $t_1 \duntap t_2$ exploits the continuity of nominal tactics to divide up the name store between t_1 and t_2:

$$\frac{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash t_1]\!]_\rho \equiv T_1 \quad \mathcal{M} [\![\Upsilon \parallel \Gamma \vdash t_2]\!]_\rho \equiv T_2}{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash t_1 \duntap t_2]\!]_\rho \equiv \lambda \alpha.\mathtt{THEN}(T_1(\alpha), \lambda J.T_2([\mathtt{M}(T_1)(J, \alpha)]\overline{\alpha}, J))}$$

Next, we define the behavior of the sequencing tactical, by case on the multi-tactical:

$$\frac{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash t_1]\!]_\rho \equiv T_1 \quad \mathcal{M} [\![\Upsilon, \vec{u} : \mathtt{hyp} \parallel \Gamma \vdash t_2]\!]_\rho \equiv T_2}{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash \vec{u} \leftarrow t_1; \Box t_2]\!]_\rho \equiv \lambda \alpha.\mathtt{THEN}(T_1(\vec{u} \oplus \alpha), \lambda J.T_2([\mathtt{M}(T_1)(J, \vec{u} \oplus \alpha)]\overline{\vec{u} \oplus \alpha}, J))}$$

$$\frac{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash t]\!]_\rho \equiv T \quad \mathcal{M} [\![\Upsilon, \vec{u} : \mathtt{hyp} \parallel \Gamma \vdash t_i]\!]_\rho \equiv T_i \quad (i < n)}{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash \vec{u} \leftarrow t; (\!|t_0, \ldots, t_n|\!)]\!]_\rho \equiv \lambda \alpha.\mathtt{THENL}(T(\vec{u} \oplus \alpha), [\lambda J.T_i([\mathtt{M}(T)(J, \vec{u} \oplus \alpha)]\overline{\vec{u} \oplus \alpha}, J) \mid i < n])}$$

$$\frac{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash t_1]\!]_\rho \equiv T_1 \quad \mathcal{M} [\![\Upsilon, \vec{u} : \mathtt{hyp} \parallel \Gamma \vdash t_2]\!]_\rho \equiv T_2}{\mathcal{M} [\![\Upsilon \parallel \Gamma \vdash \vec{u} \leftarrow t_1; \Diamond_i t_2]\!]_\rho \equiv \lambda \alpha.\mathtt{THENF}(T_1(\vec{u} \oplus \alpha), i, \lambda J.T_2([\mathtt{M}(T_1)(J, \vec{u} \oplus \alpha)]\overline{\vec{u} \oplus \alpha}, J))}$$
